## The scenario

- Let's have two clocks which are synchronized according to Einstein's procedure in each of two inertial frames of reference.
- Let the clocks be a proper distance $d$ from each other in their respective frames.
- Let the frames move with the relative speed $v$.

Figure 1: The frames of reference
There are three events of interest:

Event $\boldsymbol{E}_{\mathbf{1}}$ : clock $A$ and clock $A^{\prime}$ are adjacent
Event $\boldsymbol{E}_{\mathbf{2}}$ : clock $A$ and clock $B^{\prime}$ are adjacent
Event $\boldsymbol{E}_{\mathbf{3}}$ : clock $B$ and clock $A^{\prime}$ are adjacent

## Calculation of what the clocks will show at the events

## Event $\boldsymbol{E}_{\mathbf{1}}$ :

$A$ shows $t_{1}=0, A^{\prime}$ shows $t_{1}^{\prime}=0$ (the clocks are set thus)
Event $\boldsymbol{E}_{2}$ :
In frame $K^{\prime}, A$ will be at the position $-d$ when $B^{\prime}$ shows $t_{2}^{\prime}=\frac{d}{v}$
According to the Lorentz transform, $A$ shows:

$$
\begin{equation*}
t_{2}=\frac{\frac{d}{v}+\frac{-d v}{c^{2}}}{\sqrt{1-\frac{v^{2}}{c^{2}}}}=\frac{d}{v} \sqrt{1-\frac{v^{2}}{c^{2}}} \tag{1}
\end{equation*}
$$

## Event $\boldsymbol{E}_{3}$ :

In frame $K, A^{\prime}$ will be at the position $d$ when $B$ shows $t_{3}=\frac{d}{v}$
According to the Lorentz transform, $A^{\prime}$ shows:

$$
\begin{equation*}
t_{3}^{\prime}=\frac{\frac{d}{v}-\frac{d v}{c^{2}}}{\sqrt{1-\frac{v^{2}}{c^{2}}}}=\frac{d}{v} \sqrt{1-\frac{v^{2}}{c^{2}}} \tag{2}
\end{equation*}
$$

Summing up, the readings of the clocks will be:
At event $E_{1}: \quad A$ shows $t_{1}=0 \quad A^{\prime}$ shows $t_{1}^{\prime}=0$
At event $E_{2}: \quad A$ shows $t_{2}=\frac{d}{v} \sqrt{1-\frac{v^{2}}{c^{2}}} \quad B^{\prime}$ shows $t_{2}^{\prime}=\frac{d}{v}$
At event $E_{3}: \quad B$ shows $t_{3}=\frac{d}{v} \quad \quad A^{\prime}$ shows $t_{3}^{\prime}=\frac{d}{v} \sqrt{1-\frac{v^{2}}{c^{2}}}$

The symmetry is obvious.

## Which clock is running slow or fast relative to which?

The answer depends on how the clocks are compared!
In frame $K$ we can measure the rate $\frac{\mathrm{d} t^{\prime}}{\mathrm{d} t}$ of the moving clock $A^{\prime}$ by comparing the reading of $A^{\prime}$ with the readings of the two clocks $A$ and $B$ as it passes them:

$$
\begin{equation*}
\frac{\mathrm{d} t^{\prime}}{\mathrm{d} t}=\frac{\left(t_{3}^{\prime}-t_{1}^{\prime}\right)}{\left(t_{3}-t_{1}\right)}=\sqrt{1-\frac{v^{2}}{c^{2}}} \tag{3}
\end{equation*}
$$

## Conclusion \#1: Clock $A^{\prime}$ runs slow as observed in frame $K$

In frame $K^{\prime}$ we can measure the rate $\frac{\mathrm{d} t}{\mathrm{~d} t^{\prime}}$ of the moving clock $A$ by comparing the reading of $A$ with the readings of the two clocks $A^{\prime}$ and $B^{\prime}$ as it passes them:

$$
\begin{equation*}
\frac{\mathrm{d} t}{\mathrm{~d} t^{\prime}}=\frac{\left(t_{2}-t_{1}\right)}{\left(t_{2}^{\prime}-t_{1}^{\prime}\right)}=\sqrt{1-\frac{v^{2}}{c^{2}}} \tag{4}
\end{equation*}
$$

## Conclusion \#2: Clock A runs slow as observed in frame $K^{\prime}$

This is what is meant by mutual time dilation.
Conclusion \#1 does not contradict conclusion \#2 because the temporal interval between different sets of events are compared.

## But we can draw more conclusions

We can measure the rate $R^{\prime}$ at which an observer in $K^{\prime}$ will see the co-ordinate time of $K$ runs by reading the clocks $A$ and $B$ as they pass clock $A^{\prime}$ :

$$
\begin{equation*}
R^{\prime}=\frac{\left(t_{3}-t_{1}\right)}{\left(t_{3}^{\prime}-t_{1}^{\prime}\right)}=\frac{1}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{5}
\end{equation*}
$$

Conclusion \#3: The co-ordinate time of frame $K$ runs fast as observed in frame $K^{\prime}$

We can measure the rate $R$ at which an observer in $K$ will see the co-ordinate time of $K^{\prime}$ runs by reading the clocks $A^{\prime}$ and $B^{\prime}$ as they pass clock $A$ :

$$
\begin{equation*}
R=\frac{\left(t_{2}^{\prime}-t_{1}^{\prime}\right)}{\left(t_{2}-t_{1}\right)}=\frac{1}{\sqrt{1-\frac{v^{2}}{c^{2}}}} \tag{6}
\end{equation*}
$$

Conclusion \#4: The co-ordinate time of frame $K^{\prime}$ runs fast as observed in frame $K$

There is nothing contradictory between conclusion \#3 and \#4 either.
It is in fact conclusions $\# 1$ and $\# 3$ and conclusions $\# 2$ and $\# 4$ respectively that compare the temporal interval between the same sets of events.
